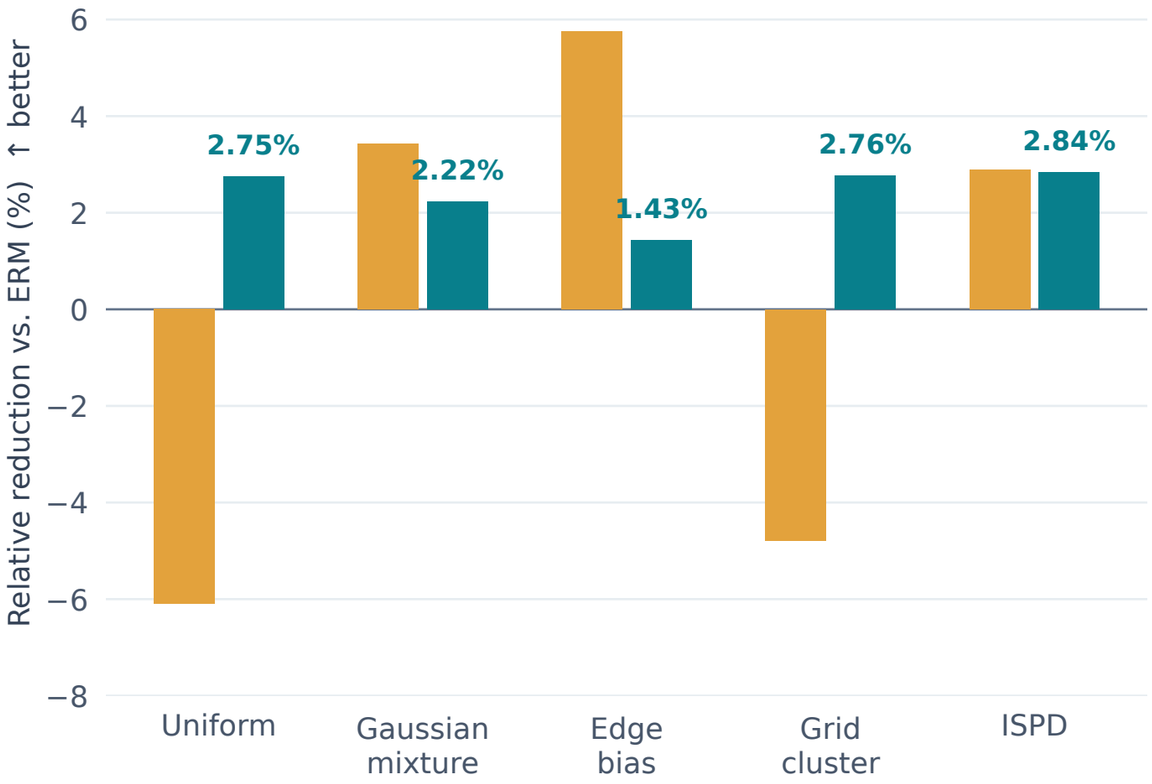
RESULTS AT A GLANCE

WDRO reduces mean regret by 1.43–2.84% versus ERM

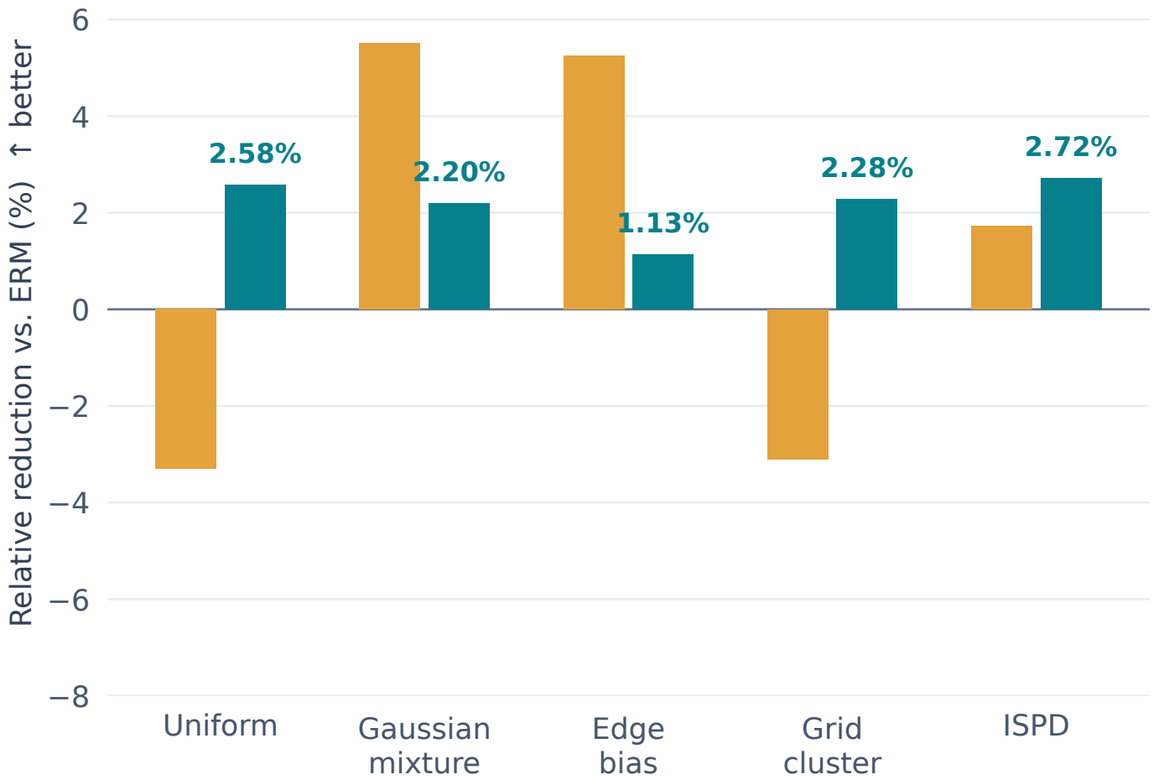
All four synthetic distributions and the ISPD test set | 3 training seeds | frozen model evaluation

Mixed ERM WDRO-REST

Mean regret reduction



P95 regret reduction



Positive = lower regret than ERM; negative = higher regret. Reduction = (ERM − method) / ERM × 100.
Synthetic: equal degree/seed weights; P95 computed within each degree/seed, then averaged. ISPD: pooled nets per seed, then seed average.
Mixed ERM is stronger on Gaussian mixture and edge bias; these results do not show WDRO superiority over every baseline.
